SYSTEM AND METHOD FOR SUPPORTING INTERACTIVE OPERATIONS
AND STORAGE MEDIUM

5 CROSS REFERENCES TO RELATED APPLICATIONS

The present document is based on Japanese Priority Document JP 2000-222895, filed in the Japanese Patent Office on July 24, 2000, the contents of which being herein incorporated by reference.

10

BACKGROUND OF THE INVENTION

1. Field of the Invention:

15 This invention relates to a system and method for supporting operations for input of user commands to household electric appliances such as a television set/monitor and information equipment, and in particular, to an interactive operation support system and a method therefor, which permit input of user commands to various kinds of connected equipment interactively.

20 More specifically, the present invention is concerned with an interactive operation support system and a method therefor, which are adapted for input of user commands to the equipment in a natural form through a personified assistant, and in particular, to an interactive operation support system
25 and a method therefor, which permit input of user commands by means of interaction with a personified assistant on a speech input base.

2. Description of the related art

30 Conventionally, an operation panel, a keyboard and a mouse or the like of a type requiring manual operation are

mainly applied to a user interface, that is, input of commands to various kinds of household electric equipment such as a television set/monitor or information equipment including a personal computer. With the improvement of operation input performance of a processor and the advance of cognitive technology including speech recognition, an interactive speech-based input user interface is now widespread as well.

Since the user interface based on the manual operation permits direct and uniform input of commands to the equipment, a user may put the input operations into practice with certainty. However, the user has to understand and further get skilled in the techniques for operating the equipment to a certain extent, and therefore, an excessive burden is required for the user.

For instance, "a fingertip operation based interface" for control a menu with a ten-key or the like is mainly used in a television and other AV equipment. However, it is to be supposed that complicated operations are required for the interface in the user input mode described in the above to deal with network-connected household electric equipment.

While a user interface using a commander is now being generalized, too numerous switches are required to meet demands for multi-channel and multi-control including ground wave band, satellite systems, the Internet and HAVI (Home Audio/Video Interoperability: common command system for digital AV equipment), resulting in an increasing number of switches, thus making operation increasingly complicated. Combination of the above user interface with a multi-function switch and a menu screen permits a reduction in number of switches up to a certain point, however operation becomes very complex.

On the other hand, the user interface on the speech input

base makes it possible to specify a command by analyzing a user request based on the result of input speech recognition on the equipment side, resulting in a relief from user's burden on the occasion of operation of the equipment. However, since
5 it is necessary for the user to speak at a microphone in the absence of a partner, such operation hardly can be considered a naturally human action. Besides, the user may be subject to suffering mental anguish when carrying out interaction with such a kind of user interface.

10 In this connection, there is recently provided an interactive operation support system, which is set to allow a personified assistant to appear on a display screen, permitting the user to perform input of commands to the equipment in the form of carrying out a conversation face to
15 face with an assistant on the screen.

In Japanese Patent Laid-open No. 11-65814, for instance, there is disclosed a user interface, which provides a sharp feeling of presence and actuality for the user by detecting a sound produced from the user or a direction of a sound source
20 to control a visual image of an imaginary creature according to the result of detection (i.e., an imaginary creature is set to follow the source of sound by constantly gazing at the source direction).

Also, in Japanese Patent Laid-open No. 11-37766, there
25 is disclosed an agent device, which provides a personified agent having functions of establishing communication with a driver in a vehicle. According to such agent device, the personified agent is set to make motions fit for the current conditions of the vehicle and the driver according to not only
30 the current conditions of the vehicle and the driver but also the learning effects based on the past history, permitting

the vehicle to establish communication with the driver.

Recently, an increase in computer processing power or the like permits a high-level interactive processing and also makes it possible to provide a sort of intelligence to the assistant on the screen. For instance, the assistant may not only operate an input command simple enough to be formed by a single word, such as a channel select command and a recording/reproduction start or stop command, but also perform complicated operations across a plurality of stages in pursuit of a context of the content of conversation with the user.

However, such a system making it possible to present the status conditions in progress related to such operations on the screen through an assistant has not been developed so far, and as a result, there is no other way other than the user having to wait for response from the system with one's eyes fixed on the screen. It is to be even supposed that if the user gives a command to the system to execute a processing requiring a response time, the user would even misunderstand that the equipment is out of order.

Thus, it is preferable that, in order to allow the user to operate the equipment based on interaction with the assistant, an operationally easy input of a command system produces an effect close to natural language is provided.

SUMMARY OF THE INVENTION

The preferred embodiments of the present invention provide a system and/or a method for supporting operations for inputting user commands to household electric equipment such as a television set/monitor and information equipment.

A preferred embodiment of the present invention provides a system and/or method for supporting interactive operations,

permitting interactive input of user commands to the equipment.

Another preferred embodiment of the present invention provides a system and/or a method for supporting interactive operations, permitting input of user commands to the equipment
5 in a natural form through a personified assistant.

A further preferred embodiment of the present invention provides a system and/or method for supporting interactive operations, permitting input of user commands by means of speech based interaction with a personified assistant.

10 A still further embodiment of the present invention provides a system and/or method for supporting interactive operations, permitting feedback of the progress conditions of operations specified by user commands inputted by means of speech based interaction with a personified assistant.

15 The preferred embodiments of the present invention are provided such that a first preferred embodiment of the present invention relates to a system for supporting interactive operations for input of user commands to electrical appliances or equipment. The system for supporting interactive
20 operations includes a display unit, a speech input unit, a speech output unit and an operation control unit, the operation control unit including an assistant control means for generating a personified assistant to allow the generated assistant to appear on a screen of the display unit, an output
25 speech control means for determining a speech required for the assistant to output the assistant's speech to the outside through the speech output unit after speech synthesis, an input speech recognition means for recognizing a user voice inputted through the speech input unit as a speech, an interaction
30 management means for managing interaction between the user and the assistant according to the assistant's speech

determined by the output speech control means and the user speech recognized by the input speech recognition means, and a command interpreting means for specifying the user's intention or the inputted user command based on the content of interaction traced by the interaction management means.

According to such preferred embodiment of the present invention, the assistant control means may also be set to determine a proper animation of the assistant based on the content of interaction managed by the interaction management means and/or the inputted user command specified by the command interpreting means.

The output speech control means may also be set to determine the assistant's speech based on the content of interaction managed by the interaction management means and/or the inputted user command specified by the command interpreting means.

The output speech control means may also be set to determine the assistant's speech suitable for leading the user's intention, when the command interpreting means fails to specify the user's intention or the inputted user command.

The system for supporting interactive operations may further comprise a connection means for connecting the external equipment such as a television set/monitor and a video deck to the system. In this case, the command interpreting means may also be set to interpret commands for control of external equipment functions inclusive of broadcasting program channel selection and recording/reproduction in the video deck or the like.

The system for supporting interactive operations may further comprise a communication means for connecting the system to a communication medium such as an external network

and a telephone line. In this case, the input speech recognition means may also be set to recognize audio data received via the communication medium.

5 The system for supporting interactive operations may further comprise a communication means for connecting the system to a communication medium such as an external network and a telephone line, and a mail exchange means for making an exchange of electronic mails via the communication medium. In this case, the output speech control means may also be set
10 to determine the assistant's speech based on the content of an incoming mail.

The interaction management means may also be set to manage an input speech of one user as a message bound for the other user. In this case, the output speech control means may also
15 be set to determine the words the assistant's speech will speak based on such message.

The assistant control means may also be set to place a personified assistant in a room (a character room) having various kinds of objects scattered around including links to
20 information resources. For example, in response to an interest of the user in a recording media including a link to a music content placed in the room, the command interpreting means may also be set to interpret an inputted user command as a command to play back the music content.

25 In response to that the command interpreting means succeeds in interpreting an inputted user command, the assistant control means may also be set to allow the assistant to appear on the screen of the display unit.

The system for supporting interactive operations may
30 further comprise a connection means for connecting a television set/monitor to the system. In this case, in response to the

command interpreting means succeeding in interpreting an inputted user command as a channel select command, the assistant control means may also be set to make appear an assistant carrying in one's hand a selected broadcasting program display window.

Otherwise, in response to a command interpreting means interpreting an inputted user command as a channel change command, the assistant control means may also be set to display changeable broadcasting program display windows in the shape of a substantial ring around the assistant. In response to that a desired channel is definitely selected by shifting the display windows in such a way as to revolve on the substantial ring under a channel change command from the user, the assistant control means may also be set to zoom up the selected broadcasting program display window.

Still, the system for supporting interactive operations may further comprise a connection means for connecting a secondary storage device for storing and reproducing a broadcasting program content to the system. The secondary storage device referred in the present invention includes a video deck, a hard disc, DVD-RAM (Digital Versatile Disk - Read Only Memory) drive, CD-R/W (Compact Disc [a trademark] - Read/Write) drive or the like media storage device capable of recording mass media contents, for instance. In this case, in response to the command interpreting means interpreting an inputted user command as a recorded program reproduction command, the assistant control means may also be set to make the assistant have a binder showing a view of recorded broadcasting program contents in one's hand to appear. In response to that, a recorded broadcasting program content selected to be reproduced is definitely selected, the assistant

control means may further be set to zoom up the selected recorded broadcasting program content display window.

5 The system for supporting interactive operations may further comprise a connection means for connecting a television set/monitor to the system. In this case, in response to that the command interpreting means succeeds in interpreting an inputted user command as a channel change command, the assistant control means may also be set to allow the assistant with a list of changeable broadcasting programs arranged in a matrix shape in one's hand to appear. In response to that a desired channel is definitely selected, the assistant control means may further be set to zoom up the selected broadcasting program display window. Further, EPG (Electronic Programming Guide) distributed as a part of data broadcast may be applied to generate the list of broadcasting programs in the matrix shape.

15 The system for supporting interactive operations may further include a connection means for connecting a television set/monitor to the system, a communication means for connecting the system to a communication medium such as an external network and a telephone line, and a mail exchange means for making an exchange of electronic mails via the communication medium. In this case, the assistant control means may also be set to allow an incoming mail display image to appear on the screen of the display unit, in response to the acceptance of a mail.

25 The system for supporting interactive operations may further comprise a text or character conversion means for converting ideograms like Japanese Kanji or the like, relating to text data displayed on the screen of the display, unit into phonetic characters like Japanese Kana or the like, or still vice-versa.

30 The system for supporting interactive operations may

further have a communication means for connecting the system to a communication medium such as an external network and a telephone line and a certifying means for certifying an information terminal connected to the system via the communication medium.

The system for supporting interactive operations may further comprise a connection means for connecting a television set/monitor to the system, and an extraction means for extracting text information from a received broadcasting program content. In this case, the text information extracted by the extraction means may also be superimposed on the content of a different broadcasting program now being projected on the screen.

A second preferred embodiment of the present invention relates to a method for supporting interactive operations, and this method is applied to the equipment including a display unit, a speech input unit and a speech output unit for supporting input of user commands to the equipment or other externally connected equipment. The method for supporting interactive operations includes an assistant control step for generating a personified assistant to allow the generated assistant to appear on a screen of the display unit, an output speech control step for determining a speech required for the assistant to output the assistant's speech to the outside through the speech output unit after speech synthesis, an input speech recognition step for recognizing a user voice inputted through the speech input unit as a speech, an interaction management step for managing interaction between the user and the assistant according to the assistant's speech determined by the output speech control step and the user speech recognized by the input speech recognition step, and a command interpreting step for

specifying the user's intention or the inputted user command based on the content of interaction traced by the interaction management step.

5 According to the preferred embodiment of the present invention, the assistant control step may also be set to determine a proper animation of the assistant based on the content of interaction managed by the interaction management step and/or the inputted user command specified by the command interpreting step.

10 The output speech control step may also be set to determine the assistant's speech based on the content of interaction managed by the interaction management step and/or the inputted user command specified by the command interpreting step.

15 The output speech control step may also be set to determine the assistant's speech suitable for leading the user's intention, when the command interpreting step fails to specify the user's intention or the inputted user command.

20 When the equipment further includes a connection means for connecting the external equipment such as a television set/monitor and a video deck to the equipment, the command interpreting step may also be set to interpret commands for controlling of external equipment functions including a broadcasting program channel selection and/or recording/reproduction in the video deck or the like.

25 When the equipment further includes a communication means for connecting the equipment to a communication medium such as an external network and a telephone line, the input speech recognition step may also be set to recognize audio data received via the communication medium.

30 When the equipment further includes a communication means for connecting the equipment to a communication medium

such as an external network and a telephone line, and a mail exchange means for making an exchange of electronic mails via the communication medium, the output speech control step may also be set to determine the assistant's speech based on the
5 content of an incoming mail.

The interaction management step may also be set to manage an input speech of one user as a message bound for the other user, and the output speech control step may also be set to determine the assistant's speech based on the message.

10 The assistant control step may also be set to place a personified assistant in a room scattered with various kinds of objects including links to information resources. In response to the interest of the user in a recording media including a link to a music content placed in the room, for
15 instance, the command interpreting step may also be set to interpret an inputted user command as a command to play back the music content.

In response to the command interpreting step succeeding in interpreting an inputted user command, the assistant control
20 step may also be set to allow the assistant to appear on the screen of the display unit.

When the equipment further includes a connection means for connecting a television set/monitor to the equipment, in response to the command interpreting step succeeding in
25 interpreting an inputted user command as a channel select command, the assistant control step may also be set to allow the assistant with the selected broadcasting program display window in one's hand to appear.

Otherwise, in response to the command interpreting step
30 succeeding in interpreting an inputted user command as a channel change command, the assistant control step may also be set

to display changeable broadcasting program display windows in a ring-shaped form around the assistant. In response to a desired channel selected by shifting the display window in such a way as to move on the ring-shaped form under a channel
5 change command from the user, the assistant control step may further be set to zoom up the selected broadcasting program display window.

When the equipment further includes a connecting means for connecting a secondary storage device for storing and
10 reproducing a broadcasting program content to the equipment, in response to that the command interpreting step succeeds in interpreting an inputted user command as a recorded program reproduction command, the assistant control step may also be set to allow the assistant with a binder showing a view of
15 recorded broadcasting program contents in one's hand to appear. In response to that a recorded broadcasting program content desired to reproduce is definitely selected, the assistant control step may further be set to zoom up the selected recorded broadcasting program content display window. The secondary
20 storage device referred to the present invention includes a hard disc, DVD-RAM drive, CD-R/W drive or the like media storage device capable of recording of mass media contents, in addition to the video deck.

When the equipment further includes a connection means
25 for connecting a television set/monitor to the equipment, in response to that the command interpreting step succeeds in interpreting an inputted user command as a channel change command, the assistant control step may also be set to allow the assistant with a list of changeable broadcasting programs
30 arranged in a matrix shape in one's hand to appear. In response to that a desired channel is definitely selected, the assistant

control step may further be set to zoom up the selected
broadcasting program display window. Further, EPG
(Electronic Programming Guide) distributed as a part of data
broadcast may be applied to generate the list of broadcasting
5 programs in the matrix shape.

When the equipment further includes a connection means
for connecting a television set/monitor to the equipment, a
communication means for connecting the equipment to a
communication medium such as an external network and a
10 telephone line, and a mail exchange means for making an exchange
of electronic mails via the communication medium, the assistant
control step may also be set to allow an incoming mail display
image to appear on the screen of the display unit in response
to the acceptance of a mail.

15 The method for supporting interactive operations may
further include a text conversion step for converting, for
example, a Japanese ideogram Kanji related to text data
displayed on the screen of the display unit into a phonetic
symbol, like Japanese Kana. This can be applied for conversion
20 of displayed data of one system or group of characters or codes
into another system or group of characters or codes.

The method for supporting interactive operations may
further include a communication step for connecting the
equipment to a communication medium such as an external network
25 and a telephone line, and a certifying step for certifying
an information terminal connected to the equipment via the
communication medium.

When the equipment further includes a connection means
for connecting a television set/monitor to the equipment, the
30 method for supporting interactive operations may further
comprise an extraction step for extracting text information

from a received broadcasting program content. The text information extracted by the extraction step may also be superimposed on the content of a different broadcasting program currently projected on the screen.

5 A third preferred embodiment of the present invention relates to a storage medium, in which computer software describing the interactive operation support processing for execution on a computer system is stored physically in a computer readable form, the interactive operation support
10 processing being applied to equipment including a display unit, a speech input unit and a speech output unit for supporting input of user commands to the equipment or other externally connected equipment. The computer software of the storage medium includes an assistant control step for generating a
15 personified assistant for making the generated assistant to appear on a screen of the display unit, an output speech control step for determining a speech required for the assistant to output the assistant's speech to the outside through the speech output unit after speech synthesis, an input speech
20 recognition step for recognizing a user voice inputted through the speech input unit as a speech, an interaction management step for managing interaction between the user and the assistant according to the assistant's speech determined by the output speech control step and the user speech recognized by the input
25 speech recognition step, and a command interpreting step for specifying the user's intention or the inputted user command based on a content of interaction traced by the interaction management step.

The storage medium according to the third preferred
30 embodiment of the present invention refers to a medium, which provides physically the computer software, in a computer

readable form, for a general-purpose computer system permitting various program codes to be executed, for instance. The above storage medium includes CD (Compact Disc - a trademark), FD (Floppy Disc - a trademark), MO (Magneto-optical Disc) or any other detachable and portable storage medium, for instance. The above storage medium may also technically provide the computer software for a specific computer system in a computer readable form via transmission medium such as a network (no matter whether such network is of a cable or a wireless type) or the like.

The above storage medium is constructed in accordance with definition of the structural or functional cooperative relation between the computer software and the storage medium for the purpose of performing the predetermined computer software functions on the computer system. In other words, installation of the predetermined computer software into the computer system through the storage medium according to the third preferred embodiment of the present invention makes it possible to perform cooperative functions on the computer system and as a result, may produce the functional effects similar to those of the system or method for supporting interactive operations according to the first or second preferred embodiment of the present invention.

According to the system and method for supporting interactive operations of the present invention, applying the animated character called a personified assistant making reactions based on speech analysis and animations to the user interface permits the user to feel friendly toward the user interface and simultaneously makes it possible to meet a demand for complicated commands or to provide an entry into services for the user. Further, since there is provided a command system

producing an effect close to natural language, the user may easily operate the equipment with the same feeling as ordinary human conversation.

5

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing and other objects and features of the invention will become apparent from the following description of preferred embodiments of the invention with reference to the accompanying drawings, in which:

10

Fig. 1 schematically illustrates the hardware configuration of a system 1 for supporting interactive operations for use in a preferred embodiment of the present invention;

15

Fig. 2 shows a command processing system in the interactive operation support system 1 according to a preferred embodiment of the present invention;

Fig. 3 shows a character control system in the interactive operation support system 1 according to a preferred embodiment of the present invention;

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Fig. 1 schematically illustrates a hardware configuration of a system 1 for supporting interactive operations for use in a preferred embodiment of the present invention. The system 1 is configured as a receiving device for a television set/monitor such as STB (Set Top Box), for instance, and is connected to the television set/monitor. The system 1 may provide support services of user operations such as channel selection and recording/reproduction by carrying on interaction with a user through the mediation of an assistant, which will be described later, to interpret explicit or latent user's intention based on the interaction. A description will now be given of each unit with reference to Fig. 1.

A central control unit 11 refers to an operation control unit for controlling the operations in the interactive operation support system 1 generally according to a predetermined control program and performs the processing of generating an assistant as a partner for the user, allowing action patterns of the assistant to appear and managing the interaction between the user and the assistant based on input/output of speeches and images, for instance.

The following functions are contained in the control program executed in the central control unit 11, for instance. That is:

- (1) Operational control of each unit in the system 1 according to an inputted user command resulting from recognition of a speech inputted through a microphone 22;
- (2) Control of various kinds of external equipment connected to the system through an input/output interface 17;
- (3) Control of a tuner 15;
- (4) Character control relating to the assistant (generation

of the animation corresponding to the input command resulting from speech recognition);

(5) Speech synthesis (conversion of audio data produced from the character into an audio signal. Provided that
5 synchronization of the animation of character lip motions or the like with a speech is required.);

(6) Control of connection or the like of the system to an external network through a communication interface 18;

(7) Control of EPG (Electronic Programming Guide) and other
10 data for data broadcast;

(8) Control of output of a speech through a speaker 21;

(9) Control of display on a screen through a monitor 25;

(10) Control according to the inputted command through a remote controller (not shown);

(11) Processing of text data for use in electronic mails, EPG and a wide area network;

(12) Conversion of text data based on user profiles (for converting Kanji into Kana for children, for example);

(13) Image measurement based on data accompanying a video
20 signal (for extracting information relating to the progress of scoring on the sports programs such as a baseball game and a soccer game and time information from a program content displayed on the screen) and various kinds of services based on image recognition (for informing the user about the
25 information related to the progress of scoring and also to set time information or the like);

(14) Bit map conversion requiring a font selected from a font database based on text data;

(15) Combination of texture selected from a texture database
30 with a font bit map; and

(16) Basic settings of the system (including screen

brightness, sound volume and various kinds of input/output operations).

A tuner 15 performs tuning of broadcast wave of a predetermined channel, that is, channel selection according to a command from the central control unit 11. The received broadcast wave is separated into a video data portion and an audio data portion. The video data is outputted to the monitor 25 through an image processing unit 16 for display on the screen, while the audio data is outputted to the speaker 21 through a speech synthesis unit 14 for production of sounds (alternatively, line output will be enough as well).

A storage device 12 is used for storage of data required for generation of images and action patterns of the assistant. The following information is included in the data stored, for instance. That is:

- (1) 3D-character image information of the assistant and data required for generating the animation of the assistant;
- (2) Layout and other information relating to a character room adapted to bring the assistant into action;
- (3) User profile information of the user who carries on the interaction with the assistant;
- (4) History of user-assistant conversations in the past and other interchanges, and character/feeling and learning data based on the history; and
- (5) Advertising contents to be mapped into the assistant or the character room.

The storage device 12 also performs storage of various kinds of databases (not shown) such as a font database and a texture database, in addition to storage of information relating to the assistant. The font database is used for management of various kinds of fonts required for EPG, an

electronic message board and an electronic mail or the like.
The texture database is used for management of various kinds
of textures (2D-bit map data or the like) required for the
EPG, the electronic bulletin board and the electronic mail
5 or the like.

While it doesn't matter that the system 1 is set to make
only a single assistant to appear, a different assistant may
also be provided for each user. That is, a plurality of
characters different in age, sex and character are available
10 for the system 1 to automatically select the characters
according to the user profile on the occasion of initial log-in
or to permit the user to select the characters for making an
entry of the selected character in association with the user
profile or the like. Otherwise, assistant learning/history
15 data may also be provided for each user, so that the same
assistant, even if needed, is set to make different reactions
according to each user.

The speech recognition unit 13 performs recognition of
an audio signal, i.e., a user speech supplied through a speech
20 input device such as the microphone 22 as text information,
before analysis of an inputted user command converted into
a text format with the use of a language database (not shown).
More specifically, the processing of dividing a text into word
units through morpheme analysis to gain language information
25 such as syntactic information and conversational information
through syntactic/semantic analysis is performed to
understand the inputted user command or the like, which is
then outputted to the central control unit 11.

The input/output interface 17 refers to a device for
30 connecting the external equipment such as a video deck 23 and
a personal computer (PC) 24 to the system 1. One or more AV

equipment and information equipment may be connected externally to the system 1 according to interface specification such as i-link (IEEE1394), for instance.

5 The communication interface 18 refers to a device for mutually connecting the system 1 to other host computer systems on an external network. The external network is equivalent to a wide area network such as the Internet, for instance. On the network, there are provided various kinds of servers such as a WWW (World Wide Web) server to distribute WWW resources described in HTML format, a mail server to distribute mail exchange services to each user account and an advertising server to distribute advertising contents updated every moment. In the embodiment of the present invention, it is to be understood that at least one of the servers on the network should be a character server to distribute character data of images, animations and character/action models relating to the assistant required for support of interactive operations for free or paid service.

10 In addition to the above servers, the network also involves an information distribution server such as "Season Database" constructed by collecting public institution services or the like, "Weekly" to distribute a weather report, a broadcasting program guide or the like every week, "Daily" to distribute news and advertisement or the like highly instantaneous information every day and "Timely" to distribute constantly changing information like stock quotations, exchange rate and traffic information, a commerce server to distribute services of physical distribution sales and settlement of accounts (electronic settlement of accounts) and an Internet service provider or the like.

30 In case of a TCP/IP (Transmission Control

Protocol/Internet Protocol) network, for instance, since the resources distributed from each server are identified in URL (Uniform Resource Locator) format, the system 1 may download these information resources according to a predetermined
5 protocol such as HTTP (Hyper Text Transfer Protocol). Thus, the interactive operation support system 1 according to the embodiment of the present invention may update the images and character/functions or the like of the assistant by re-downloading the active character data cyclically or at the
10 desired timing.

Transactions executable by the interactive operation support system 1 via the network are given as follows:

- (1) To update a control program for driving each unit in the system 1;
- 15 (2) To download a character constituting the assistant;
- (3) To download font data;
- (4) To download texture data;
- (5) To issue a request to substitute program recording for a recording means (video tape or like media, for instance)
20 which is not provided although desired (Refer to "Recording substituting system" disclosed in Japanese Patent Laid-open No. 2000-162320 already assigned to the present applicants);
- (6) To analyze a user profile and to user-customize;
- (7) To utilize public institution services;
- 25 (8) To acquire a weather report, a program guide, news, traffic information and advertisement or the like;
- (9) Electronic commercial transactions;
- (10) Character control via the network (with the use of a speech, an electronic mail and a control Web page or the like).

30 A modem 19 refers to a device for transferring digital computer data via a public telephone line such as PSTN (Public

Switched Telephone Network) and performs modulation into an analog signal and demodulation into a digital signal.

A telephone installed in each house is connected to the public telephone line through a switchboard, for instance.

5 The public telephone line is also connected to a wireless telephone network. Thus, the interactive operation support system 1 according to the preferred embodiment of the present invention permits exchange of data to and from the installed telephone and a mobile telephone. The assistant automatically
10 generated in the central control unit 11 may also be set to interpret inputted user commands based on the interaction with the user through the mobile telephone.

The central control unit 11 gives effect to perform the interaction between the user and the system 1 by controlling
15 the operations in the system 1 in accordance with the result of speech recognition by the speech recognition unit 13.

When the input user speech is interpreted as a conversation with the assistant, for instance, the central control unit 11 determines assistant reactions based on a speech
20 and animations after determining the motions of the assistant according to learning/history data and the action models relating to the assistant.

The assistant's speech is outputted to the outside through the speaker 41 after being synthesized by the speech
25 synthesis unit 14. When a sound of a program now being on the air is produced, the assistant's speech may also be outputted after being superposed with the sound.

The assistant motion is synthesized with an image by an image processing unit 16 with reference to 3D-character
30 information and animation information. At this event, a background (scene) can be changed over with reference to

character room information, when occasion demands. Otherwise,
an assistant image or a character room, where the assistant
is found, may be displayed in the state of superposition with
the contents of one or more programs now being on the air (which
5 will be described later in detail).

When the input user speech is interpreted as a channel
change command, the central control unit 11 transfers a channel
number to the tuner 15 for channel selection.

When the input user speech is interpreted as a command
10 (start and end of recording and reproduction operations, fast
forward, rewind and playback from each head and file transfer,
for instance) to the external equipment such as the video deck
23 and the personal computer 24, the central control unit 11
issues a required command to the associated equipment via the
15 input/output interface 17.

When the user input speech is interpreted as a command
for access to the wide area network, the central control unit
11 transfers a request for access to a specified host system
on the network via the communication interface 18. When the
20 network refers to TCP/IP network such as the Internet, for
instance, the request for access is described in URL format.
In such a case, the user may read up URL or may utter few words
(a home page title, for instance) uniquely related to URL.
In the latter case, the speech inputted through the assistant
25 is converted into URL after being recognized.

The system 1 may also be set to accept an inputted user
command from a remote controller (not shown), similarly to
the conventional AV equipment. In such a case, a unit for
receiving wireless (infrared) data transmitted from the remote
30 controller and a decoder for interpreting data received are
required, and decoded data and commands are processed in the

central control unit 11.

The interactive operation support system 1 according to the preferred embodiment of the present invention is characterized by performing input of commands from the user on a speech base by carrying on the interactive processing through the medium of the assistant generated on the screen of the monitor 25. The assistant referred to the embodiment is a 3D-character having animation functions. The interactive processing is set to involve the processing of interpreting a user-assistant conversation (a daily conversation) to extract user commands and that of providing user feedback through assistant reactions.

According to the interactive operation support system 1 of the preferred embodiment of the present invention, applying the personified assistant making reactions based on speech synthesis and animations to the user interface permits the user to feel friendly toward the user interface, and simultaneously makes it possible to meet a demand for complicated commands or to provide an entry into services for the user. Further, since the interactive operation support system 1 has the command system producing an effect close to natural human language, the user may easily operate the equipment with the same feeling as ordinary conversations.

Fig. 2 shows a command processing system in the interactive operation support system 1 according to the preferred embodiment of the present invention.

In the speech recognition unit 13, the user speech inputted through the microphone is recognized as text information, and further, the inputted user command converted into a text format is analyzed with the use of a language database (not shown).

In the preferred embodiment of the present invention, commands provided as practicable commands include "Character control" for generating assistant motions in response to the inputted user command, "Equipment control" for instructing
5 the video deck and other external equipment connected to the system 1 to operate, "Speech synthesis" for generating an assistant's speech in response to the inputted user command, "Mail" for making an exchange of mails through the network and "Bulletin board" for making an exchange of messages among
10 a plurality of (unspecified) users or the like.

"Character control" refers to a command to control the system 1 and the equipment externally connected thereto in cooperation with the assistant motions (in other words, with the assistant motions as feedback) in response to the inputted
15 user command on a speech base.

Fig. 3 illustrates a character control system in the interactive operation support system 1 according to the preferred embodiment of the present invention.

As shown in Fig. 3, the system 1 may perform function
20 commands such as "Channel selection", "Channel change", "AV equipment control", "Mail read", "Mail write", "Bulletin board read", "Bulletin board write" and "Ambient" through character control.

In this embodiment, "Ambient" means the functions of
25 setting the character constituting the assistant to make motions in a proper way or to act as if urging the user to input commands by means of speech synthesis when the system is placed in the wait state.

Synchronization of speech with animation for automatic
30 lip sync (pronouncing lip shape) is preferably required for the system 1 to perform "Mail read" and "Bulletin read" or

the like functions of setting the character to read up text information.

The procedure of performing the function commands through character control will be described below.

5 The character is set to inform the user about the current status by means of speech synthesis or the like. The system 1, when remote-controlled by the user via the network or through the mobile telephone, may apply an electronic mail or the like means to inform the user about the status.

10 Instead of a single character constituting the assistant, characters customized individually every user may also be provided for the same interactive operation support system 1. A type or model and animation of each character can be updated or changed through a communication means such as a
15 network, a recording media or broadcasting, for instance. Further, advertising or other information contents may be dynamically mapped into clothes texture of each character.

Fig. 4 illustrates a basic configuration required for the command processing on a speech base in the interactive
20 operation support system 1 according to a preferred embodiment of the present invention.

The speech inputted through the microphone 22 is converted into text base information after being recognized by the speech recognition unit 13.

25 The central control unit 11 performs the processing of interaction with the user based on the text information to understand the user command given in the form close to a natural language.

The central control unit 11 then controls the operation
30 of the AV equipment externally connected to the interactive operation support system 1 according to the result of command

interpreting. In addition, the central control unit 11 permits user feedback of the conditions of execution of the commands by means of speech synthesis or by generating character animation.

5 A description will now be given of some embodiments relating to the command interpretive processing carried by the interactive operation support system 1 on the speech input base according to the preferred embodiment of the present invention.

10 [Embodiment 1]

 An input user speech in Japanese, "Video 1 kara Video 2 ni dubbing shite", which is English equivalent to a command of "Dub a recorded content in Video 1 into Video 2", is processed as follows.

15 → The system 1 converts the input user speech into text and further divides into lexical units of "Video", "1", "kara", "Video", "2", "ni", "dubbing" and "shite".

 → The system 1 further sorts this command form into two kinds of lexical units, that is, one representing two kinds of equipment specified by "Video", "1" and "2" and the other representing a single command specified by "dubbing".

20 → The system 1 then analyses these lexical units to generate an equipment control command of "Video" "1" "kara" "Video" "2" "ni" "dubbing", which is English equivalent to a command of "Dub a recorded content in Video 1 into Video 2".

 [Embodiment 2]

 An input user speech in Japanese, "Video wo Dubbing", which is English equivalent to a command of "Dub a recorded content in Video", is processed as follows.

30 → The system 1 divides the input user speech into lexical

units of "video", "wo" and "dubbing".

→ Since the lexical unit representing a command specified by "dubbing" is contained in this command form, it may be supposed that there are two kinds of equipment. Then, the system 1 provides, for the user, a speech representing a question stating that from which video to which video. In response to the question from the system, a command of "Video 1 kara Video 2 e", which is English equivalent to a command of "From Video 1 to Video 2", is given from the user to the system.

→ The system 1 further divides the above command form into lexical units of "Video", "1", "kara", "Video", "2" and "e".

→ After reinput of lexical units insufficient for lexical interpretation, the system 1 generates a command of "Video 1 kara Video 2 e dubbing", which is English equivalent to a command of "Dub a recorded content in Video 1 into Video 2".

[Embodiment 3]

An entry of synonyms is required for lexical interpretation to cope with a wide-ranging mode of expression.

For instance, a lexical unit of "1 channel" covers all the following modes of expression in the Tokyo area.

"Ichi"
"Ichani"
"Ichannel"
"Sogo"
"Sogo TV"
"NHK sogo"
"NHK sogo TV"
"NHK"

--- --- ---
[Embodiment 4]

The command forms are classified into single, double, triple command forms or the like.

5 The single command form refers to a command formed by a single lexical unit such as "NHK" and "Yon-channel", for instance.

 The double command form is composed of lexical units representing the single equipment and a single command form.
10 For instance, a command composed of lexical units of "Television", "rokuga" and "shite" (provided that omission of "shite" is possible), which are English equivalent to a command of "Record a television program" and a command composed of lexical units of "Rokuga", "shitamonoo" and "misete", which
15 are English equivalent to a command of "Playback recorded program content", are involved in the double command form.

 The triple command form is composed of lexical units representing two kinds of equipment and a single command form. For instance, a command composed of lexical units of "Video",
20 "1", "kara", "Video" "2", "ni" and "dubbing", which are English equivalent to a command of "Dub a recorded content in Video 1 into Video 2", and a command composed of lexical units of "DVD", "wo", "Video", "1", "ni" and "Copy", which are English equivalent to a command of "Dub a recorded content in DVD into
25 Video 1" and so on are involved in the triple command form.

 Fig. 5 schematically shows a flow of the character control processing.

 When the power of the television monitor 25 is turned on, the character constituting the assistant begins operating.
30 The assistant is set to sit and wait in a living room (or one's private room), for instance, for input of function commands

a cheerful boy, who lives inside the Television set and is growing up day after day.

Since he inhabits the Television set, he is well acquainted with everything about the Television as a matter
5 of course and also can control most of the equipment connected to the Television.

Since he is a curious boy, various kinds of things are put in his room, and up-to-date information also lies scattered around in his room.

10 He sometimes makes meaningless motions too. (Well, he must make allowance for his childhood.)

Although it seems that he has friends or companions, persons who succeeded in gaining access to his friends or companions are limited yet.

15 Well, suppose that he is a good-natured boy, in other words, a pretty interface.

The "Yoshio's" room is scattered with various kinds of objects such as magazines and toys, for instance. These objects have references of links to various services such as
20 advertising and merchandizing services (including distribution of data content and music content in addition to physical shopping). That is, user-accessible objects are scattered about the room, and it comes to this, that the scattered objects suggest that the user may gain access to
25 what kind of things, if speaking something.

The system 1 permits the user to utilize advertising and other information resources by providing the room for the assistant. The assistant, if set to derive the user profile through the interaction with the user, makes it possible to
30 meet a demand for more carefully throughout services. The assistant may also be set to cope with user's peculiar way

of expression and speaking or the like.

For instance, if the user speaks to "Yoshio" about one's interested object, the input user speech is recognized and then interpreted as a command, and information resources, to
5 which the target object is link-referred, are called. The objects scattered over in the room or the assistant clothes may be changed everyday.

When the system 1 is set to store a performable music content in advance, CDs and a CD player may be provided as
10 the accessible objects in the "Yoshio's" room. In this case, each of scattered CDs (a recording media) has a link to the associated music content. When a question of "What kind of CD is this?" is put to "Yoshio" by the user, the system 1 may make an answer like "This is ○△." through "Yoshio" (Refer
15 to Fig. 7), before starting playback of the music content just as being performed with the use of the CD player displayed on the screen.

Otherwise, in response to a question of "What kind of CD is this" put to "Yoshio" by the user on condition that CDs
20 relating to a hit chart are provided as accessible objects displayed on the floor of the "Yoshio's" room, the system 1 may judge the user to have an interest in musical pieces of the hit chart, before issuing a request for purchase of a CD (on-line shopping) or the like to a predetermined server or
25 downloading the required music content from a predetermined site.

In the embodiment shown in Fig. 6, a poster of an automobile is provided as the accessible object displayed on the wall surface of "Yoshio's" room. The poster provided for
30 the room as described the above refers to an advertising medium or reference of link to the advertising medium. For instance,

the system 1 may induce the user to buy or present advertising information to the user by means of speaking to the user through the assistant.

In the embodiment shown in Fig. 6, a globe is also provided
5 as the accessible object displayed in the "Yoshio's" room. An information distribution system developed in a global scale, that is, metaphor called WWW may be provided for the globe. In this case, speaking to "Yoshio" about the terrestrial globe activates a WWW browser (not shown), permitting WWW search.

10 In the embodiment shown in Fig. 6, a television set/monitor is also provided as the accessible object displayed in the "Yoshio's" room. This television set/monitor has metaphor about the real television monitor 25 and may be set to project a broadcasting program on the last channel (that
15 is, a last selected channel) (in the embodiment shown, a program on "Channel B" as the last selected channel is being projected).

Although not shown in Fig. 6, a mailbox may also be provided as the accessible object displayed in the "Yoshio's" room. The mailbox is metaphor about a tray of accepting
20 electronic mails and may be set to provide a mail display image in the mailbox when accepted mails are stored.

Incidentally, instead of direct access to the display screen showing the "Yoshio's" room after the application of power, the system 1 may be set to permit the user to gain access
25 to "Yoshio's" room in response to an input of a user speech or a remote controller operation.

According to the interactive operation support system 1 in the preferred embodiment of the present invention, applying the assistant called "Yoshio" to the user interface permits
30 the user to feel friendly toward the user interface, and simultaneously makes it possible to meet a demand for

complicated commands or to provide an entry into services for the user.

A description will now be given of various kinds of operation support processing according to the interactive operation support system 1, which applies the assistant making reactions based on speech synthesis and 3D-animation to the user interface.

(1) Television power ON/OFF

It is assumed that in the power OFF state of the television (provided that the system 1 is in operation), the user speaks to the assistant in a natural language form, like "Turn on television, Yoshio!".

The input user speech described the above is recognized and then interpreted as a command in the speech recognition unit 13, permitting the turning the power of the television on.

The "Yoshio's" room as shown in Fig. 6, for instance, may be set to appear on the initial screen immediately after the application of power. Or, some kinds of variations of a way to make a "Yoshio's" appearance on the screen may be provided for the user to selectively use an appropriate way for each user or according to the environment of the user or the weather conditions. The following variations of the way for making an assistant's appearance may be given, for instance.

• "Yoshio" appears in the "Yoshio's" room with such words as "Hi" and "Jaan".

• "Yoshio" is wandering around his room in silence.

• "Yoshio" goes into the ambient state delightfully with such words as "Ah" or "Well".

In this stage, a user speech to the effect that "I want to watch television", when further provided to the assistant,

is recognized and then interpreted as a command in the speech recognition unit 13. Then, the system 1 makes an affirmative answer such as "OK" and "All right" in a speech output form through "Yoshio", and simultaneously, a program on the last
5 channel (that is, a channel having been selected the last time the power was turned off) is projected in such a way as to be zoomed up. For instance, the system may be set to operate the virtual television set/monitor provided in the "Yoshio's" room in such a way that after the program on the last channel
10 (as described the above) is projected on the virtual television set/monitor, the virtual television monitor screen is gradually zoomed up so as to eventually occupy the whole area of a real monitor screen.

On the other hand, speaking to the assistant in a natural
15 language form, like "Turn off television, Yoshio!" will be enough for the user to turn off the television power.

The input user speech as described the above is recognized and then interpreted as a command in the speech recognition unit 13, permitting disconnection of television power.

20 For the period between the acceptance of input command and the power turn off, the system 1 may also provide a dramatic presentation for the user in such a way that "Yoshio" appears on the screen, then recedes toward the depth of the screen with his back turned with a somewhat sad look and finally
25 disappears from the screen.

(2) Channel selection

Channel selection is classified into direct channel selection that a specific channel is selected explicitly by the user and zapping channel selection that anything the user
30 likes is selected out of programs being now on the air without explicit selection of a specific channel.

Direct channel selection:

In direct channel selection, since a desired channel is specified on the bases of input of user speech, operationally easy input of a command system producing an effect close to natural language is preferably required for the user.

According to the preferred embodiment of the present invention, applying the assistant called "Yoshio" to the user interface permits the user to feel friendly toward the user interface and simultaneously makes it possible to meet a demand for complicated commands or to provide an entry into services for the user. A more natural interface may be constructed by means of interaction with the personified assistant, which is set to ask back the user about an uncomprehensible part, when it is not sufficient to interpret the user's intention so far as the first input of the user speech, for instance.

Embodiments of direct channel selection operation are given in the following.

(Embodiment 1)

User: "Turn on NHK, Yoshio! Channel 1."

"Yoshio": ("Yoshio" appears and asks back.)
"NHK? Channel 1?"

User: "Yes (an affirmative answer)"

"Yoshio": ("Yoshio" waits for the subsequent input of user speech.)

"Yoshio" then disappears (in response to that there was no input of user speech for a predetermined period of time).

(Embodiment 2)

User: "Turn on "Kyoiku", Yoshio! Channel 3."

"Yoshio": ("Yoshio" appears and asks back.)

"Kyoiku? Channel 3?"

User: "Yes (an affirmative answer)"

"Yoshio": ("Yoshio" waits for the subsequent input of user speech.)

"Yoshio" then disappears (in response to that there was no input of user speech for a predetermined period of time).

5 (Embodiment 3)

User: "Turn on Nihon TV, Yoshio! Channel 4."

"Yoshio": ("Yoshio" appears and asks back.)

"Nihon TV? Channel 4?"

User: "Yes (an affirmative answer)"

10 "Yoshio": ("Yoshio" waits for the subsequent input of user speech.)

"Yoshio" then disappears (in response to that there was no input of user speech for a predetermined period of time).

(Embodiment 4)

15 User: "Turn on TBS, Yoshio! Channel 6."

"Yoshio": ("Yoshio" appears and asks back.)

"TBS? Channel 6?"

User: "Yes (an affirmative answer)"

"Yoshio": ("Yoshio" waits for the subsequent input of user speech.)

20 "Yoshio" then disappears (in response to that there was no input of user speech for a predetermined period of time).

(Embodiment 5)

User: "Turn on Fuji TV, Yoshio! Channel 8."

25 "Yoshio": ("Yoshio" appears and asks back.)

"Fuji TV? Channel 8?"

User: "Yes (an affirmative answer)"

"Yoshio": ("Yoshio" waits for the subsequent input of user speech.)

30 "Yoshio" then disappears (in response to that there was no input of user speech for a predetermined period of time).

(Embodiment 6)

User: "Turn on TV Asahi, Yoshio! Channel 10."

"Yoshio": ("Yoshio" appears and asks back.)

"TV Asahi? Channel 10?"

5 User: "Yes (an affirmative answer)"

"Yoshio": ("Yoshio" waits for the subsequent input of user speech.)

"Yoshio" then disappears (in response to that there was no input of user speech for a predetermined period of time).

10 (Embodiment 7)

User: "Turn on TV Tokyo, Yoshio! Channel 12."

"Yoshio": ("Yoshio" appears and asks back.)

"TV Tokyo? Channel 12?"

User: "Yes (an affirmative answer)."

15 "Yoshio": ("Yoshio" waits for the subsequent input of user speech.)

"Yoshio" then disappears (in response to that there was no input of user speech for a predetermined period of time).

Fig. 8 to Fig. 11 illustrate display of a screen, when
20 direct channel select operation is performed through the assistant.

First, it is assumed that the user of the interactive operation support system 1 is watching a baseball-game relay program now being on the air, as a viewer of the television.
25 (Refer to Fig. 8). While the above program is being projected, the user may put direct channel selection into practice through the assistant by speaking explicitly to the assistant about a desired channel name, like "Turn on Channel 8, Yoshio!", "Turn on Fuji TV, Yoshio!" or "Fuji TV".

30 The input user speech is recognized and then interpreted as a command in the speech recognition unit 13. Then, "Yoshio"

as the assistant with a panel (or a window) displaying the program currently on the air on the specified channel in one's hand appears on the monitor screen (Refer to Fig. 9). In this state, the destination channel is placed in the temporarily
5 selected state yet.

Then, the assistant makes a request for making sure of the user command by means of output of a speech, like "This one?". When an affirmative answer such as "Yes" is given from the user side in response to the request, the destination
10 channel is changed from the temporarily selected state to the definitely selected state.

In response to that the desired channel is definitely selected, the screen is scrolled as if the assistant pushes out a panel displaying the program on the source channel (i.e.,
15 the baseball-game relay program in this embodiment) to the right in the drawing, so that a panel displaying a program currently on the air on the destination channel (Channel 8, in this embodiment) gradually comes out from behind the previous panel (Refer to Figs. 10 and 11.).

It is to be understood that a mode of clearing away the display panel of the program on the source channel is not particularly limited to scrolling of the screen in the lateral direction as shown in Fig. 10. For instance, the screen may be scrolled as if "Yoshio" as the assistant pushes the display
20 panel of the program on the source channel downward or upward.
25

Figs. 8 to 11 illustrate the direct channel selection in a visually easy style by means of displaying the programs respectively being on the air on the source channel and the destination channel simultaneously on the single monitor
30 screen. A multiple-decoding function may be applied to perform simultaneous display of two or more broadcasting programs.

Incidentally, mapping logo-type and advertising information into the clothes or the like of the assistant making an appearance on the display screen for direct channel selection has an effect on advertising. As a matter of course, the clothes
5 of the assistant may be changed according to the season.

Fig. 12 is a flow chart showing the procedure of implementing the user interface based on a direct command form. According to the above procedure, the interactive operation support system 1 may implement a more natural user interface
10 by means of interaction with the personified assistant, which is set to ask back the user about a part, which is difficult to understand so far as the first input of the user speech. A description will now be given of the procedure with reference to the flow chart of Fig. 12.

15 Firstly, the user speech inputted through the microphone 22 is recognized in the speech recognition unit 13 to extract an input keyword, in Step S1.

Subsequently, by retrieving the databases provided for each category, a user command corresponding to the input user
20 speech is specified in Step S2. The databases classified by categories are stored in the storage device 12, for instance, and the contents thereof may be updated via the network.

When it is not sufficient to specify the user command so far as the input of the user speech up to now, the decision
25 for block S3 is selected as "NO" in order to asking back the user about insufficient information by outputting a speech through the mediation of the assistant, in Step S5. Then, the processing is returned to Step S1 in order to wait for the subsequent input of a user speech.

30 On the other hand, when the user command is specified by the input of the user speech up to now, the system issues

a required command to the equipment corresponding to the user command (the television monitor 25 and the video deck 26 or the like, for instance) , in Step S4. Then, the processing is returned to Step S1 in order to wait for the subsequent
5 input of a user speech.

Zapping channel selection

When zapping channel selection is required, the user puts input of a command, like "Show me programs on all the channels, Yoshio!" or "What program is showing now, Yoshio?"
10 to the assistant into practice without selecting a specific channel.

In response to the user command on the speech base as described the above, the assistant, that is, "Yoshio" makes an appearance on the monitor screen to display a multi-view
15 screen permitting the user to watch all the programs currently on the air in one view.

Fig. 13 shows the multi-view screen, which permits the user to watch the programs currently on the air on the respective channels in one view. In the embodiment shown in Fig. 13,
20 panels displaying the programs currently on the air on the respective channels are placed in the shape of a ring in the room of "Yoshio" as the assistant so as to enclose "Yoshio". Immediately after change to the multi-view screen, the leading panel may be set to display the program currently on the air
25 on the last channel (that is, the last selected channel), for instance.

On the multi-view screen as described in the above, the user can give a command by speaking closely to a natural language form to "Yoshio" as the assistant.

30 The program display panels are set to be shifted in sequence on the ring in such a way that in response to a command,

which specifies the channel, like "Turn on Channel 12", "Channel 12", "Turn on TV Tokyo" and "TV Tokyo", the display panel of the program on the specified channel may come to the forefront of the monitor screen. Further, in response to a command like
5 "one before (or previous)" and "next one (next)", the program display panels may be shifted forward or backward one by one over the ring (Refer to Fig. 14).

Fig. 15 shows a virtual view from the above showing the state of the multi-view screen. As shown in Fig.15, the
10 program display panels are placed at substantially uniform intervals along the ring, which is adapted for shift of the program display panels, in the "Yoshio's" room. The display panel of the program on the channel temporarily selected is placed at the forefront of the ring.

As shown in Fig. 15, a part of the ring has a gap with
15 no program display panels. Since the gap is shifted in sequence together with the program display panels along the ring according to the channel shift command from the user, the user may grasp visually the shift of the channels, while following
20 up the shift position of the gap with one's eyes.

After the lapse of a predetermined period of time (several seconds, for instance) with a certain program display panel staying at the forefront of the screen, the corresponding channel goes into the temporarily selected state, and the
25 display panel of the program on the temporarily selected channel is highlighted. Fig. 16 shows a channel C, which is highlighted after being put in the temporarily selected state.

When the display panel of the program on a desired channel comes to the forefront of the screen, the user may definitely
30 select the temporarily selected channel by emphatically speaking to the assistant about the selected channel, like

"That", "That one", "Show me that" and "Show me this one".

After the desired channel is definitely selected, the selected channel is tuned, and simultaneously, the display panel of the program on the selected channel is zoomed up
5 gradually so as to occupy the whole monitor screen in the end.

Fig. 17 shows the state, in which after transition of channel C from the temporarily selected state to the definitely selected state, the display panel of the program on the definitely selected channel is gradually zoomed up.

10 Fig. 13 illustrates zapping channel selection in a visually easy style on the multi-view screen by means of displaying the programs currently on the air on the respective channels simultaneously on the single monitor screen. A multiple-decoding function may be applied to perform
15 simultaneous display of two or more broadcasting programs.

Incidentally, each program display panel appearing on the multi-view screen is not always necessary to display the program currently on the air. For instance, display of reproduced program contents taken out from recorded data stored
20 in the video deck or other storage device is also applicable.

(3) Recording

The interactive operation support system 1 according to the preferred embodiment of the present invention is connected to one or more video decks 23 as the external equipment
25 and therefore, may specify the video decks as the destination of recording of the received broadcasting program. Also, the internal storage device 12 configured by a hard disc drive may also be specified as the destination of recording.

The interactive operation support system 1 according
30 to the preferred embodiment of the present invention may provide a more natural user interface by means of interaction on a

speech base through the mediation of the personified assistant. Thus, the user may give a desired program recording command by speaking to the assistant in a nearly natural language form without depending on conventional equipment operations such
5 as the remote controller or the like.

Fig. 18 shows a state in which a program recording command on a speech basis is given to the assistant.

As shown in Fig. 18A, it is assumed that the user is currently watching the baseball-game relay program, for
10 instance. At any time when making a request for recording the program currently on the air as described in the above, the user can give a command by speaking to the assistant, like "Record this program", or "Record this", etc.

The inputted user speech is recognized and then
15 interpreted as a command in the speech recognition unit 13, and as a result, the system 1 specifies the input command as a request for recording the program currently on the air.

Then, the system 1 searches a free area in the externally connected video deck 23 or the built-in hard disc. After making
20 sure of the destination of recording, the system 1 gives an affirmative answer of "Yes" or the like to the user through the assistant by means of speech synthesis.

As shown in Fig. 18B, a recording icon representing that a program is now recording is displayed on the monitor screen,
25 together with a counter representing a recording time.

(4) Recording of programs scheduled to broadcast

The interactive operation support system 1 also permits recording of programs scheduled to broadcast, that is, reserved recording, in addition to the programs currently on the air.

30 The interactive operation support system 1 according to the preferred embodiment of the present invention may provide

a more natural user interface by means of interaction on a speech basis through the mediation of a personified assistant. Thus, the user may give a recording reservation command by speaking to the assistant in a nearly natural language form without depending on the remote controller or the like conventional equipment operations.

Fig. 23 and Fig. 24 illustrate display of a screen, when recording reservation is set through the assistant.

It is assumed that the user makes input of speech suitable for deriving information relating to scheduled programs, such as "What program is starting from now? Yoshio!", "What comes next? Yoshio!", "Show me EPG (Electronic Programming Guide), Yoshio!" or "What program is starting from 8:00? Yoshio!" to the system through the assistant.

The input user speech is recognized and then interpreted as a command in the speech recognition unit 13. Then, "Yoshio" as the assistant provides display of a list of programs scheduled to broadcast in the form of a matrix (Refer to Fig. 23). The EPG distributed as data for data broadcast, for instance, may be used to generate the list of programs.

The assistant may also be set to read up the list of programs after being displayed on the monitor screen as shown in Fig. 23.

The user may determine easily a desired program to record from the programs displayed in the form of a list. Then, the user gives a command to the system by speaking to "Yoshio" as the assistant in the natural language form, like "Record a program scheduled to be on the air from 8:00 on Channel D".

The input user speech is recognized and then interpreted as a command in the speech recognition unit 13. Then, the selected channel D is highlighted. "Yoshio" as the assistant

outputs a speech suitable for urging the user to make sure of the selected channel, like "Is this one?", while pointing at a column of channel C.

When an affirmative answer is given from the user in response to the request to make sure of or confirm the selected channel, reserved recording is set. In this case, the system 1 may be set not only to highlight the column of the specified program for recording but also to display a recording reserve icon (not shown).

10 (5) Reproduction of recorded program content

The interactive operation support system 1 according to the embodiment of the present invention may provide a more natural user interface by means of interaction on a speech basis through the mediation of the personified assistant. Thus, the user may give not only a desired program recording command, but also a recorded program reproduction command by speaking to the assistant in the natural language form without depending on the remote controller or the like conventional equipment operations.

20 When a random-accessible storage device such as a hard disc device is applied to the destination of program recording, an arbitrary recorded program content may be taken out before start of reproduction.

Fig. 19 to Fig. 22 illustrate display of a screen, when reproduction of a recorded program content is performed through the assistant.

Firstly, it is assumed that the user of the interactive operation support system 1 is watching a musical program currently on the air as a viewer of the television (Refer to Fig. 19). While the program is being on the air, the user may give a reproduction command to the system by explicitly

speaking to the assistant about reproduction of a recorded program content, like "Reproduce a recorded program" or "Reproduce a recorded video".

5 The input user speech is recognized and then interpreted as a command in the speech recognition unit 13. "Yoshio" as the assistant provides a display image of a binder having the contents (thumbnail) of the recorded programs (Refer to Fig. 20).

10 The user may specify a recorded program content desired to reproduce with the thumbnail the recorded program contents displayed in the binder form as a key. Then, reading up the desired program content to reproduce, like "Channel G" is enough.

15 The input user speech is recognized and then interpreted as a command in the speech recognition unit 13. Then, the thumbnail of a target recorded program content is highlighted, while being zoomed up (Refer to Fig. 21).

20 The user may make sure of the target recorded program content for reproduction with zoomed-up thumbnail display as a key. Then, the user may give a reproduction start command by speaking to the assistant in the natural language form like "This one" and "That one" to the system through "Yoshio". The input user speech is recognized and then interpreted as a command in the speech recognition unit 13. A speech
25 representing an affirmative answer such as "Yes" is produced from the system through "Yoshio" (Refer to Fig. 22).

Then, the thumbnail of the target recorded program content for reproduction is zoomed up so as to occupy the whole monitor screen, and reproduction of the target recorded program
30 content is started.

Incidentally, the system 1 may also be set to specify

reproduction of a recorded program content on a daily basis,
in addition to the above recorded program selecting mode. A
scenario in such case is given briefly in the following.

User: "Reproduce program contents having been recorded
5 yesterday, Yoshio."

→ The display panels of the programs contents having
been recorded yesterday are revolving around "Yoshio" (Refer
to Fig. 25).

User: "Reproduce a program content on Channel C."

10 "Yoshio": "Is this one?"

User: "Yes" (Refer to Fig. 26).

→ The specified program display panel is gradually
zoomed up so as to occupy the whole screen, and reproduction
of the specified program content is started (not shown).

15 (6) Mail

As shown in Fig. 1, the interactive operation support
system 1 according to the embodiment of the present invention
is connected to the external network via the communication
interface 18, and therefore, permits exchange of mails by making
20 use of the mail server on the network.

The interactive operation support system 1 according
to the embodiment of the present invention also permits exchange
of mails by means of interaction on a speech base through the
medium of the personified assistant. The acceptance of mails
25 through support by the assistant on a speech base will be
described in the following.

Upon acceptance of mails while the program is being now
on the air, the system 1 displays, on the program content,
an envelop icon informing the user that the mail is accepted
30 in such a way as to flutter down through the program content
(Refer to Fig. 27).

Then, the envelop icon, when reaching the lower end of the monitor screen, disappears, while an incoming mail icon representing how many mails are accepted appears on the top right-hand side of the screen. In the embodiment shown in
5 Fig. 28, there is shown a case where a piece of mail is accepted.

The user may give a command to open a mailbox by speaking to the assistant in the natural language form like "Show me a mail, Yoshio!", for instance. That is, the input user speech is recognized and then interpreted as a command in the speech
10 recognition unit 13. Then, "Yoshio" as the assistant makes motions to open the mail. The assistant may also be set to read up the text described in the mail after interpreting and speech synthesis.

Incidentally, the system 1 may also be set to convert
15 original text data from Japanese ideograms Kanji into phonetic characters Kana for making it easy for children to read in case of displaying the mail on the monitor screen. Further, the system 1 makes it possible to provide the operational environment simpler than that searching silk printed
20 characters of a button by means of speech control for aged people having difficulties for reading.

Moreover, another preferred embodiment of the present invention may establish conversion of text data from characters or codes of a system to a set of characters or codes of another
25 system, like conversion of codes or characters between different languages or different alphabet systems, for example.

Further, a mail display window wall pattern may be customized for each user. For instance, changing over a mail
30 wall paper pattern depending on whether an out-going source is user's father, mother, child or a friend permits the user

to grasp at sight who is an out-going source or sender. As
a matter of course, changeover of a character font is sufficient
for this purpose as well.

Fig. 30 is a flow chart showing the procedure for
5 displaying the accepted mail on the monitor screen. A
description will now be given for the processing of displaying
the accepted mail with reference to the flow chart shown in
Fig. 30.

Firstly, text data contained in the accepted mail body
10 is extracted, in Step S11.

Subsequently, a ideogram Kanji contained in the text
data is converted into corresponding phonetic character(s)
Kana, in Step S12. In this stage, all Kanji is not always
necessarily converted into Kana. The system 1 may also be
15 set to judge whether conversion into Kana is required based
on the user age and other user profiles or preferences, for
instance.

Subsequently, the text data converted into Kana is
expanded into bit map information by making use of a font
20 database, in Step S13. A plurality of kinds of font databases
is stored in the storage device 12, for instance. A required
font database may be selected with reference to the user
profile.

Then, the text expanded into the bit map information
25 is superposed with a texture serving as a so-called wall pattern
for synthesis of a mail display image to be projected onto
the monitor screen, in Step S14. A plurality of kinds of texture
databases is stored in the storage device 12, for instance.
A required texture may also be selected with reference to the
30 user profile.

(7) Message (Bulletin board)

A message exchange system requiring a computer such as BBS (Bulletin Board System) has been already generalized in information processing/information communication fields.

In the conventional message bulletin board system of this type, each user needs to write a message on a character input base onto a bulletin board provided by a specific server, whereby the system permits the other user to read this message.

On the other hand, according to a message bulletin board provided by the interactive operation support system 1 in the preferred embodiment of the present invention, input of messages and open-to-public of the messages may be performed by means of interaction on a speech base through the medium of the personified assistant. In input of a message from one user, instructions to the assistant that the input message is bound for a particular destination permits the assistant to read up the message for only the particular destination.

Some embodiments of scenario of messages according to the message bulletin board performed by the interactive operation support system 1 in the embodiment of the present invention are given in the following (Refer to Fig. 31).

(Embodiment)

Mother (User1): "Hi, Yoshio, I will go shopping for a while. I will be back at 6:00."

(She goes out.)

25 Takuro (User 2): "I'm home. Mother" (Takuro (her child) goes back to home.)

Takuro: "There?" (He understands that his mother is absent.)

Takuro: "Do you know where is my mother? Yoshio!"

"Yoshio" (Assistant): "Your mother is going shopping now. She will be back soon".

Takuro: "I see, thank you."

(8) Services

The interactive operation support system 1 according to the preferred embodiment of the present invention may establish communication with the user by means of interaction
5 on a speech base through the medium of the personified assistant.

The input user speech is not always limited to commands for the system 1 and the equipment such as the video deck externally connected to the system. For instance, interaction
10 in a conversation form is established. Some embodiments of the user-assistant interaction of this type are given in the following.

(Embodiment 1)

User: "How will be the weather tomorrow?"

15 "Yoshio": "It will rain (He speaks in a sad tone.)."

(Embodiment 2)

User: "Do you think there is heavy traffic on Chuo Highway? Yoshio?"

"Yoshio": "Well, so, so (He speaks in a cool tone.)."

20 (Embodiment 3)

User: "What time is it now? Yoshio"

"Yoshio": " --- (He shows his wristwatch to the user in silence.)"

(Embodiment 4)

25 User: "What time is it now in San Francisco? Yoshio"

"Yoshio": " --- (He shows to the user his wristwatch on his glove patterned with Stars and Stripes in silence.)"

(Embodiment 5)

User: "Hi, Yoshio"

30 "Yoshio": "What is the matter?"

User: "Don't forget to call me at 6:00 tomorrow morning"

"Yoshio": "Why"

User: "I have to join an important meeting".

Yoshio I see."

--- --- ---

5 (Television is turned on at 6:00 in the next morning.)

"Yoshio": "Good morning. You will join an important meeting, won't you?"

(Embodiment 6)

User: "Hi, Yoshio, I'm hungry."

10 "Yoshio": "I suppose that the Pizza shop is still open. May I ask to place an order?"

(9) Remote control

15 The interactive operation support system 1 according to the preferred embodiment of the present invention permits an exchange of data to or from the installed telephone or the mobile telephone via the modem 18 or the public telephone line (as already described in the above). Similarly, the system 1 is connected to a wide area network such as internet via the communication interface 18, and therefore, also permits
20 exchange of data to or from a remote information terminal such as a personal computer.

25 Thus, the personified assistant provided by the interactive operation support system 1 permits establishment of communication with the user by carrying on interaction on a speech base with the user through the remote terminal such as the personal computer and the mobile telephone. For instance, the system may accept an operation command for the external equipment such as the video deck through the mobile telephone.

30 Provided that acceptance of the inputted user command from the remote place without restriction may be in danger

of infringing user's privacy or indoor security. In this connection, the interactive operation support system 1 is set to make a demand for input of certificate information for making sure of the legality of the user on the side of the remote
5 information terminal such as a mobile telephone and a personal computer. A medium such as an ID card, for instance, may be available for input of the certificate information. On the other hand, input of a speech and data accepted to the system 1 through a certifying device is interpreted as commands into
10 execution (Refer to Fig. 32).

An embodiment of scenario in acceptance of remote control from the user through the personified assistant to the interactive operation support system 1 according to the preferred embodiment of the present invention is given in the
15 following (Refer to Figs. 33 to 35).

(Embodiment)

User: "Is Yoshio there? (The user makes a mobile telephone call to user's home.)"

"Yoshio": "Yes, I am on the line."

20 User: "Record a program starting from 8:00 today on Channel NHK."

"Yoshio": "A program starting from 8:00 on Channel NHK?"

User: "Yes"

"Yoshio": "OK"

25 (10) Extraction of text information from the content of a program currently on the air

The interactive operation support system 1 according to the preferred embodiment of the present invention includes a tuner 15 for channel selection, that is, tuning of the
30 broadcast wave of a predetermined channel. The received broadcast wave is separated into video data portion and audio

data portion. The video data is outputted to the monitor 25 through an image processing unit 16 for display on the screen, while the audio data is outputted to a speaker 21 through a speech synthesis unit 14 for production of sounds.

5 Decoded video data sometimes contains text information such as superimposition annexed to the program content, in addition to the principal content of the program. For instance, information relating to the progress of scoring in a sports event relay program such as a baseball game, a soccer game
10 or the like and time information is included.

For instance, it is assumed that there is a demand for information relating to the progress of a game, when a sports program is currently on the air on a different channel.

The interactive operation support system 1 according
15 to the preferred embodiment of the present invention is provided with a plurality of channel selection functions of the tuner to receive and decode sports program as a program on a different channel by using a channel selection function which is opened while a program on a certain channel is being selected. Then,
20 the decoded video data is measured and recognized for extraction of text information associated with the progress of scoring. The system 1 may also be set to allow the personified assistant to read up the extracted text information or to inform the user of the extracted text information in the form of
25 superimposition or a sub window displayed on the content of the program currently projected on the screen.

Fig. 36 is a flow chart showing the procedure of informing the user of the text information contained in a program on the different channel. A description will now be given of
30 the processing of informing the user of the text information with reference to the flow chart of Fig. 36.

Firstly, a score display area is extracted from broadcasting video data, in Step S21.

Subsequently, pattern matching is performed to extract score information from the score display area, Step S22.

5 Pattern matching of the whole video data is also applicable to search the associated text information. However, as shown in Fig. 37, since the score display area is usually placed at a substantially same location, it is possible to find the displayed score easily and fast with the location
10 of the score display area as a key.

Subsequently, it is decided whether or not the extracted score information is changed from the previous result of extraction, in Step S23.

When a change of score information occurs, the system
15 informs the user about the change of score information, in Step S24. The change of score information may be informed by means of a speech of the personified assistant through the speech synthesis, for instance, or may be displayed on the screen by means of a sub-window, a 3D display, texture and
20 2-D alpha-blending.

On the other hand, when the score information remains unchanged, the processing is returned to Step S21 to repeatedly execute a similar processing to the above. Incidentally, the system may also be set to inform the user of the score information
25 at a predetermined time interval, even if the score information remains unchanged.

According to the similar method to the above, displayed time information may be extracted from the program content, in addition to the score information of the sports program.

30 For instance, when the user is watching the television program containing displayed time information, or a plurality

of tuners are provided to monitor the program containing displayed time information on the different channel by the use of a spare tuner, time information may be measured according to an image measurement/recognition technique.

5 For instance, when a plurality of external equipment is locally connected to the single interactive operation support system 1, or remote-connected through a communication medium such as a home network, the operation of setting time information of all the equipment right is important whereas
10 being complicated. However, no accurate synchronization of current time information with one another among the equipment brings about malfunctions. For instance, when time information on the tuner side is not correct in case of reserved recording of a program, the system may fail to record the
15 program.

On the other hand, according to the interactive operation support system 1 of the preferred embodiment of the present invention, automatic setting of current time information of the television monitor 25 or the other externally connected
20 equipment may be performed by measuring the current time through the image measurement/recognition processing, when the user is watching the television program containing displayed time information, or the tuner is provided with a plurality of channel select functions to decode a program containing
25 displayed time information on the different channel by the use of the spare tuner.

Fig. 38 is a flow chart showing the procedure of setting time information based on the time information displayed on the broadcasting program content. A description will now be
30 given of the procedure of setting the time information with reference to the flow chart of Fig. 38.

Firstly, a time display area is extracted from broadcasting video data, in Step S31.

Subsequently, pattern matching is performed to extract time information from the time display area, in Step S32.

5 Pattern matching of the whole video data is also applicable to search the associated text information. However, as shown in Fig. 39, the time display area is usually placed at the substantially same location in actuality, it is possible to search the displayed time information at high speed with
10 the location of the time display area as a key.

Subsequently, it is decided whether or not extracted time information is changed from the previous result of extraction, in Step S33.

When change of time information occurs, the system sets
15 the extracted time information as the current time, Step S34. The other connected external equipment is also set to display the extracted time information, in Step S35.

On the other hand, when the time data remains unchanged, the processing is returned to Step S31 to repeatedly execute
20 the similar processing to the above.

As has been described in the foregoing, the present invention makes it possible to provide the system and method for supporting operations for input of user commands to the household electric equipment such as the television
25 set/monitor and the information equipment.

The present invention further makes it possible to provide the system and method for supporting interactive operations, permitting input of user commands to the equipment interactively.

30 The present invention still further makes it possible to provide a system and method for supporting interactive

operations, permitting input of user commands to equipment or apparatuses in a nearly naturally human form through the personified assistant.

The present invention yet further makes it possible to
5 provide a system and method for supporting interactive operations, permitting input of user commands by means of the interaction with the personified assistant on the speech input base.

The present invention yet further makes it possible to
10 provide the system and method for supporting interactive operations, permitting feedback of the progress conditions of operations specified by the user commands inputted by means of the interaction with the assistant on the speech input base to the user.

15 While the present invention has been described in detail with reference to the specific preferred embodiments, it is to be understood that modifications and variations are apparent to those skilled in the art without departing from the scope and spirits of the present invention.

20 While the description in the present specification has been given based on the preferred embodiments, in which the interactive operation support system according to the present invention is applied to television operations, it is to be understood that the scope of application of the present
25 invention is not limited to the above embodiments. The present invention may also have effects on the same kind of household electric equipment and information equipment having the function of generating and displaying the personified assistant, that of inputting, recognizing and synthesizing
30 speech and that of carrying on a conversation with the user on a speech base.

In other words, the present invention is illustrative in its preferred form and not restrictive.
